Nuclear Shape of ER+ Breast Tumor Whole Slide Images Predict Recurrence and Survival

Daniel Shao

Mentored by Dr. Anant Madabhushi, Dr. Cheng Lu

Case Western Reserve University

Center for Computational Imaging and Personalized Diagnostics

Breast Cancer Prognosis

Surgical removal

How aggressive is the tumor?

Lymph Node Involvement

Receptor status

Tumor Pathology

Quantitative Analysis

Computer-analyzed features

Machine Learning

Motivation

Challenges of Machine Learning approach:

Region of interest

Feature relevance

Is Multiple Instance Learning appropriate?

- finds most indicative region on image

How prognostic is nuclear shape?

+

-

Design

Five 2000x2000 patches
from tumor regions of WSI

→ Nuclear Segmentation

→ Feature extraction of
120 nuclear features

→ Feature Selection

↓
Model Training

↓
Evaluation

Simplifying Multiple Instances

Intuition: get one feature vector per patient

Negative patients: all patches are informative

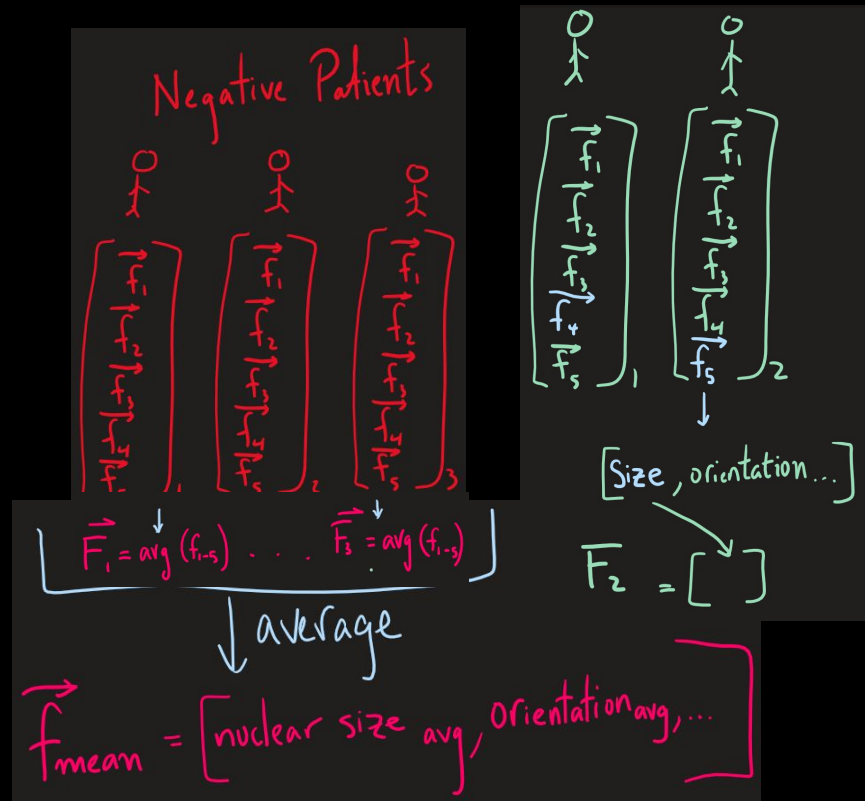

Positive patients: most different patch

Computation:

Construct vector F of feature values for each patient

Negative patients: mean feature of all patches

Positive patients: Most distant patch from mean of negatives

Training and Evaluation

**TCGA dataset
(n=665)**

**ECOG dataset
(n=245)**

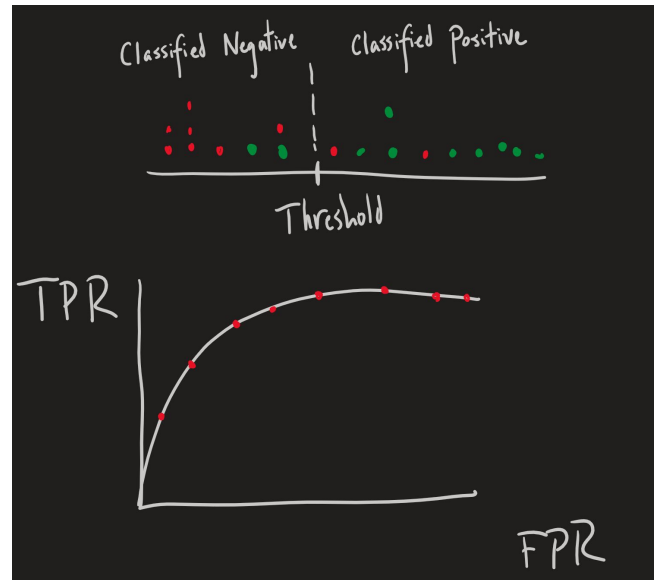

Evaluation

Construct Receiver Operating Curve

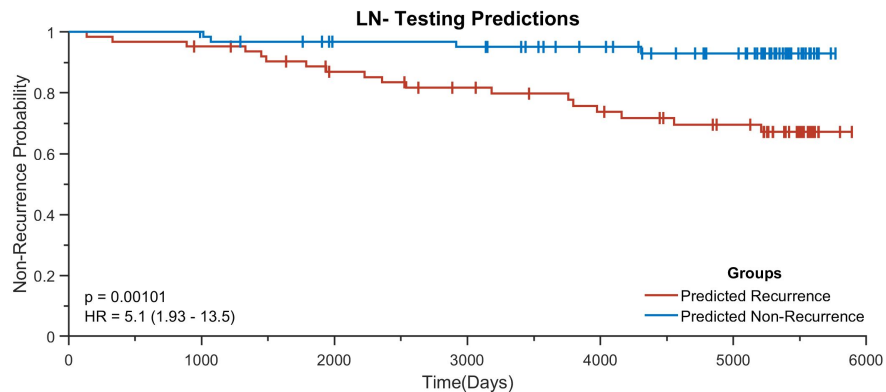

Threshold = unique feature values in F

for each threshold, get coordinate (TPR, FPR)

construct line from coordinates and compute area under curve

Kaplan-Meier survival analysis

LN Status of Train/Test set	Multivariate Hazard Ratio (95% Confidence Interval), p-value
LN-	HR=4.64 (1.32 – 16.3) p=0.017
LN+	HR=2.36 (1.09 – 5.11) p=0.029

HER2 status, PR status, tumor grade, size, age

Discussion

- Multiple Instance Learning appropriate
- Nuclear shape an independent prognostic
- Nuclear size, orientation, texture, and contour most discriminative
- Lymph node negative survival better correlated to nuclear shape
